

# Lecture 18: Network Layer

## – Control Plane II

Sejong University Spring 2019: Computer Networks

2019. 5. 13.

Cheol Jeong

This material can only be used for students that signed up for this class at Sejong University and must not be distributed outside of the class. The contents are mainly based on the text book, “Computer Networking: A Top-Down Approach” by J. F. Kurose and K. W. Ross (7th Edition).

# Contents of Chapter 5

- ◇ Introduction
- ◇ Routing algorithms
- ◇ **Intra-AS routing in the Internet: OSPF**
- ◇ **Routing among the ISPs: BGP**
- ◇ The SDN control plane
- ◇ ICMP: The internet control message protocol
- ◇ Network management and SNMP

# Intra-AS Routing in the Internet: OSPF

## ◇ In practice,

- ◆ As the number of routers becomes large, the overhead involved in communicating, computing, and storing routing information becomes prohibitive.
- ◆ An organization should be able to operate and administer its network as it wishes.

# Intra-AS Routing in the Internet: OSPF

## ◆ Autonomous systems (ASs)

- ◆ Routers are organized into ASs, with each AS consisting of a group of routers that are under the same administrative control
- ◆ An AS is identified by its globally unique AS number (ASN) assigned by ICANN regional registries.

# Intra-AS Routing in the Internet: OSPF

## ◇ Open shortest path first (OSPF) routing

- ◆ “Open”: Publicly available
  - ◆ Cisco’s EIGRP protocol was only recently became open, after roughly 20 years as a Cisco-proprietary protocol.
- ◆ Link-state protocol that uses flooding of link-state information
- ◆ Dijkstra’s least-cost path algorithm
- ◆ Each router
  - ◆ Construct a complete topological map, i.e., a graph of the entire AS system
  - ◆ Locally run Dijkstra’s shortest-path algorithm to determine a shortest-path tree to all subnets, with itself as the root node
  - ◆ Broadcast routing information to all other routers in the AS system

# Intra-AS Routing in the Internet: OSPF

## ◆ Hierarchical OSPF

# Routing Among the ISPs: BGP

- ◇ **Border gateway protocol (BGP)**
  - ◆ In the Internet, all ASs run this inter-AS routing protocol.
  - ◆ Decentralized and asynchronous
  - ◆ Packets are routed to CIDRized prefixes, e.g., 138.16.68/22
  - ◆ External BGP (eBGP)
    - ◆ Obtain prefix reachability information from neighboring ASs
  - ◆ Internal BGP (iBGP)
    - ◆ Determine the best routes to the prefixes

# Routing Among the ISPs: BGP

## ◆ Advertising BGP route information

- ◆ Gateway router: 1c, 2a, 2c, 3a
- ◆ Internet router connects only to hosts and routers within its own AS.

# Routing Among the ISPs: BGP

## ◇ Path attributes

- ◆ **AS-PATH**: The list of ASs through which prefix advertisement has passed
- ◆ **NEXT-HOP**: The IP address of the router interface that begins the AS-PATH

## ◇ “route” = prefix + attributes

- ◆ Route 1: 2a; AS2 AS3; x
- ◆ Route 2: 3b; AS3; x

# Routing Among the ISPs: BGP

## Hot potato routing

- A selfish algorithm that chooses a local gateway that has least intra-domain cost

# Routing Among the ISPs: BGP

## ◆ Route-selection algorithm

- ◆ BGP sequentially invokes the following elimination rules until one route remains:
  - ◆ 1) The routes with the highest **local preference** values (policy decision) are selected.
  - ◆ 2) The route with the shortest AS-PATH is selected.
  - ◆ 3) The route with the closest NEXT-HOP router is selected (hot potato routing)
  - ◆ 4) The router uses BGP identifiers, e.g., the lowest value, to select the route.

# Routing Among the ISPs: BGP

## ◇ Routing policy

- ◆ A, B, C are backbone provider networks
- ◆ X, W, Y are access ISPs
- ◆ All traffic entering an ISP access network must be destined for that network.
- ◆ All traffic leaving an ISP access network must have originated in that network.
